## Resolving Alias Files Quietly

### CONTENTS

[Introduction](#)[Keeping Quiet](#)[Quiet Calls](#)[MPW Pascal](#)[MPW C](#)[References](#)[Downloadables](#)

`ResolveAliasFile` always presents the user identity dialog when mounting remote volumes. This Technical Note offers an alternative function,

`ResolveAliasFileMountOption`, which uses the previously undocumented `FollowFinderAlias` trap to resolve alias files only if the target is on a volume that has been mounted. Also included is an `IsAliasFile` routine for identifying alias files.

A new routine, `ResolveAliasWithMountFlags`, was introduced with Mac OS 8.5.

`ResolveAliasWithMountFlags` is identical to `ResolveAlias` with the exception that it provides the `mountFlags` parameter allowing callers to suppress disk switch alerts. The `mountFlags` parameter can be set to `kResolveAliasFileNoUI` to prevent any user interaction, including disk switch alerts, while the alias is being resolved. See Technote [Mac OS 8.5 Technote: Part IX](#) for usage details.

[May 01 1992]

---

## Introduction

Finder alias files are one aspect of the Macintosh human interface considered "reserved for users." The internal format of Finder alias files is intentionally undefined because it is subject to change and because Finder alias files should be neither created nor altered by applications. The Finder is the user's domain, and Finder alias files are a user convenience.

Most applications do not need to take special steps to accommodate Finder alias files. They are resolved by the Finder before they are passed to an application in an Open Documents Apple event, as well as by the Standard File Package when it creates the reply record. Occasionally an application may need to resolve alias files manually. That is normally done by calling `ResolveAliasFile`, as documented in Chapter 9 of *Inside Macintosh* Volume VI.

If a Finder alias file resolves to an item on an unmounted remote volume, `ResolveAliasFile` will attempt to mount the volume to resolve the alias. For servers, this will bring up the user identity dialog box shown on page 7-24 of *Inside Macintosh* Volume VI. For removable volumes, this will raise the "Please insert..." dialog. Presentation of a dialog may be inappropriate for the application. For example, a Standard File hook procedure that quietly opens the selected file in order to offer a preview of its contents would not want the dialog presented whenever the user selects an alias to a remote item.

## Keeping Quiet

The `ResolveAliasFileMountOption` function listed below allows an application to resolve a Finder alias file only if the alias file's target is on a currently mounted volume. If the target is unavailable and the `mountRemoteVols` parameter is false, `ResolveAliasFileMountOption` returns the error `nsvErr`. `ResolveAliasFileMountOption` operates like `ResolveAliasFile` if `mountRemoteVols` is true. `ResolveAliasFileMountOption` updates the alias file if necessary, and returns `fnfErr` if the alias file is part of a circular chain.

`ResolveAliasFileMountOption` uses the previously undocumented trap `FollowFinderAlias` to resolve the alias file's 'alis' resource. This is preferable to passing the 'alis' to `MatchAlias` because it makes no assumptions about how the alias was created or how it should be resolved. Finder aliases may actually be relative aliases rather than direct aliases. In any case, `FollowFinderAlias` will take the steps necessary to resolve them properly.

`FollowFinderAlias` should not be used except when necessary to resolve the 'alis' resource of a Finder alias file. Aliases created by applications should be resolved with the Alias Manager calls `ResolveAlias` and `MatchAlias`.

**Note:**

`FollowFinderAlias` is used internally by Apple Computer, Inc. It has not been tested for use by application software. While we do not anticipate any problems, it is the responsibility of the developer to ensure that it operates appropriately and reliably for their application.

`ResolveAliasFileMountOption` uses the function `IsAliasFile`, also listed below, to determine if a file is an alias file. In keeping with the interface of `ResolveAliasFile`, `IsAliasFile` will indicate if the specified item is a folder rather than a file.

[Back to top](#)

## Quiet Calls

To determine if an `FSSpec` points to an alias file, a folder, or neither, use `IsAliasFile`.

```
FUNCTION IsAliasFile(fileFSSpec: FSSpec;
                    VAR aliasFileFlag: BOOLEAN;
                    VAR folderFlag: BOOLEAN): OSErr;
```

`IsAliasFile` simply calls `PBGetCatInfo` to check if the `FSSpec`'s target has its directory or `isAlias` bits set. These are described in *Inside Macintosh* Volume IV, page 122, and *Inside Macintosh* Volume VI, page 9-36.

To resolve an alias file without any dialogs appearing, use `ResolveAliasFileMountOption`.

```
FUNCTION ResolveAliasFileMountOption(VAR fileFSSpec: FSSpec;
                                     resolveAliasChains: BOOLEAN;
                                     VAR targetIsFolder: BOOLEAN;
                                     VAR wasAliased: BOOLEAN;
                                     mountRemoteVols: BOOLEAN): OSErr;
```

The first four parameters of `ResolveAliasFileMountOption` are the same as those of `ResolveAliasFile`. `fileFSSpec` is the specification for a file, alias file, or folder. `resolveAliasChains` should be true if the resolution should follow down a chain of alias files. `targetIsFolder` is a return parameter that is set if the `fileFSSpec` points to or resolves to a folder. `wasAliased` returns true if the input `fileFSSpec` was for an alias file.

If the `mountRemoteVols` parameter is true, `ResolveAliasFileMountOption` will attempt to mount a volume if necessary to resolve an alias file, making the call equivalent to `ResolveAliasFile`. If `mountRemoteVols` is false and the file spec is for an alias file that resolves to a volume not currently mounted, the call will return `nsvErr` rather than attempt to mount it.

The `FollowFinderAlias` trap is intended only for resolving alias records obtained from Finder alias files.

```

FUNCTION FollowFinderAlias(fromFile: FSSpecPtr;
                           alias: AliasHandle;
                           logon: BOOLEAN;
                           VAR target: FSSpec;
                           VAR wasChanged: BOOLEAN): OSErr;

    INLINE $700F,$A823; { MOVEQ #$0F,D0; _AliasDispatch; }

```

fromFile is a pointer to a file for a first attempt at a relative resolution; pass a pointer to the alias file's FSSpec for this. alias is a handle to the alias record taken from the alias file's resources. If logon is true, the alias manager will attempt to mount a volume if necessary to complete the resolution. target will be the FSSpec found by the resolution. If wasChanged is true following the call, FollowFinderAlias has updated the alias record, and the caller should call ChangedResource and WriteResource if the updated record is to be saved in the resource file.

FollowFinderAlias does a single resolution; it does not follow a chain of alias files. FollowFinderAlias returns the same errors as MatchAlias.
