

Other attributes of the engine include:

- (i) the ability to treat graphs and arcs as equivalent when an arc label in fact denotes a graph – this gives the engine recursive power; and
- 5 (ii) the ability to create multiple instances of the same arc and execute them in parallel with management of failure of the parallel branches. I.e. when one branch of a parallel arc fails, the engine automatically fails all the other executing parallel branches.

The detailed logic of the coordination engine 210 is as follows:

10

```
Vector executionQueue // queue of nodes awaiting execution
Vector messageQueue // queue of new messages
Vector messageWaitQueue // queue of nodes awaiting messages
```

15

```
public void run() {
```

```
    Node node;
```

```
    while(running) {
```

```
        node = (Node)dequeue();
```

20

```
        node.run(this);
```

```
    }
```

```
}
```

```
void enqueue(Node node) {
```

25

```
    add node to the executionQueue
```

```
    wake up the engine if it is sleeping
```

```
}
```

```
Node dequeue() {
```

```
    Node node;
```

30

```
    Time t;
```
