

Typedefs:

Most typedefs will be usable, if you've pre-edited the range types and removed the "packed" keyword. If the Pascal range in an array was from zero, the translated one may be one short. It used to automatically add "+1" to all of them. I removed that as kludge, because the majority are translated correctly. So watch for discrepancies.

Compare the "translation" to a working C source, and compare to the Pascal original, to make them complete and correct. Or look at some typedefs in your Mac #includes headers, to see how they should be.
