## Recomposite

655363\_paste.tiff ↵641947\_paste.tiff ↵

This tool is used for recombining individual plate pages of a document page from a separated PostScript file that has been DigiScripted with *<Open PostScript>* (`;/../Document/OpenPostscript.rtf;Separated;↵`).

This tool can only be used if the current document contains plate pages and this current page is a plate page.

When using this tool, it first inquires what plate the current page holds. Then it checks the following three pages for getting the plate pages of the rest of the process colors. If, for example, the current page holds a cyan plate, the three following pages are tested for a magenta, yellow and black plate. The result is displayed in the *Recomposite* panel. The plate of the current page and its page numbers are grayed. It can not be edited. The page numbers of the other process color's plates can be modified.

### Example:

A document contains two document pages, i.e., eight plate pages stored in this sequence: Cyan, Magenta, Yellow, Black, Cyan,

Magenta, Yellow, Black. If the current page is page 1, the pages 1 to 4 (= Cyan, Magenta, Yellow, Black) would be recomposited. If you were on page 2, the pages 2 - 5 (= Magenta, Yellow, Black, Cyan) would be recomposited. In the later case, you would have to correct the page number for the cyan plate from 5 to 1.

## Resolution

The result of the recompositing process will be a new OneVision document containing the recomposited page as one OneVision-Image element. In the unit field of the *Recompose* panel, you can define the resolution for the image. The default setting is 72 dpi, which is the standard screen resolution.

## Anti-aliasing

If this option is activated, the created image will be anti-aliased, which results in smoother borders and softer transitions in the image.

Clicking the <OK> button starts recompositing the current page.

Note: You can only recomposite the plates for one document page at a time. You can not include plates with spot colors into the recombination!
