

Importing data from Excel.

Here you can read all the values from an Excel worksheet, modify them, and save them back.

Concepts shown:

- Using a Native Adapter: Usually, you will want to use a native adapter to read the data, but if you are trying to read an older file (Excel 95 or earlier), you will have to use OLE.
- Creating an Excel file manually: If you don't want/ can't use the FlexCelReport component to create a report, FlexCellImport gives you a primitive API for writing values directly. I would recommend you to not abuse this feature, and use a FlexCelReport component always that you can, but that's just me. If you use code to write to excel, your code might not as portable as it would if you had used a template.
- You can't write values on empty rows (have to insert and copy rows for that)
